

**EVALUATION OF THE INFLUENCE OF
BETA-BLOCKERS ON
THE INCIDENCE OF MALARIA**

A DISSERTATION

**SUBMITTED TO THE TAMIL NADU DR. M. G. R. MEDICAL
UNIVERSITY IN PARTIAL FULFILLMENT OF
THE REQUIREMENTS FOR THE AWARD OF THE DEGREE OF
M. D. (INTERNAL MEDICINE)**

**KILPAUK MEDICAL COLLEGE
CHENNAI**

APRIL 2004 - MARCH 2007

**KILPAUK MEDICAL COLLEGE AND
GOVERNMENT ROYAPETTAH HOSPITAL,
CHENNAI**

CERTIFICATE

This is to certify that the dissertation, '**Evaluation of the Influence of Beta-blockers on the Incidence of Malaria**' is the record of the bona fide work done by Dr. Ajay Vidyasagar V., who is undergoing training in Internal Medicine for the degree of M.D., and has been carried out by the candidate himself under my direct supervision and guidance, and is genuine.

Prof. Sakunthala, M.D.,

Head of Department,
General Medicine,
Kilpauk Medical College,
Chennai.

Dr. Somasekar D. S.,

Prof. of Gen. Medicine & Superintendent,
Govt. Royapettah Hospital,
Kilpauk Medical College,
Chennai.

August 2006.

Prof. Thiyagavalli

Kirubakaran, M.D.,

Dean,
Kilpauk Medical College,
Chennai.

ACKNOWLEDGEMENTS

I am immensely grateful to Prof. D. S. Somasekar for his expert guidance and valuable suggestions beginning from the choice of topic for the study to the analysis and compilation of the results. More than just a guide, he has been my mentor. I look up to him.

I am also thankful to Prof. Sakunthala, Head of Medicine, KMC, and Prof. Thiyagavalli Kirubakaran, Dean, KMC, for allowing me to use the resources of this institution for conducting the study.

My parents have been with me every step of the way.

I am very much obliged to the Asst. Professors of my unit - Dr.Mayilvahanan, Dr.Vasanthi and Dr.Rohini; and those of the other units. I thank them for their support and encouragement.

I would not have been able to do this study without the help and support of Dr. Aarthi. I express my sincere thanks to my colleagues Dr. Shyam, Dr. Sudha and Dr. Manu. All of them have been very understanding and cooperated in giving me the space and time to concentrate on the study.

I am grateful also to the staff of the out patient departments, the follow up clinics and the laboratory services; and of course to all the patients who cooperated in this study.

Dr. Ajay Vidyasagar V.

Chennai,

August 2006

INTRODUCTION

Malaria is a febrile illness caused by parasitic infection of RBCs and is transmitted by mosquitoes. Forty percent of the world's population lives at risk for infection and between 200 and 300 million people are afflicted each year, particularly in underdeveloped and impoverished tropical and sub-Saharan countries.

There have been repeated attempts at initially controlling, then eradicating and now again controlling the disease. Various modalities that have been attempted include development of vaccines against the parasite, research into more effective drugs, and many sets of multi-

pronged approach at controlling the vector. However, the efforts have been in vain, due either to the parasite developing resistance or because of the vectors' adaptive skills.

Researchers have found that the malarial parasite uses G proteins associated with the beta-adrenergic and adenosine receptor during entry into cells, and blocking these receptors prevented the parasite from entering the cells. Beta-blockers are drugs that are antagonistic at the beta-adrenergic receptor. They are relatively inexpensive and commonly used, usually in patients with hypertension or ischemic heart disease. Hence, one would expect the incidence of malaria to be lesser in the patient on beta-blockers. As of the time when the study was begun, there had been as yet no published data in this direction.

Thus, if found clinically significant, further research and experimentation along this track will open up new avenues, offering a novel and effective approach towards the control of malaria, especially since the chance of rapid emergence of resistance is low because of the drugs being directed at a host target.

ABSTRACT

Evaluation of the Influence of Beta-Blockers on the Incidence of Malaria

Aim To determine if usage of beta-blockers was associated with a statistically significant decrease in the incidence of malaria.

Design Prospective study.

Setting The follow up clinics of hypertension and cardiology, Govt Royapettah Hospital, during the high transmission season.

Participants The patients attending the follow up clinics.

Main outcome measures Incidence of malaria among patients on beta-blockers and those not on beta-blockers during the period of study.

Results 4400 patients were seen. 42 of 2156 patients not on beta-blockers had malaria, whereas only 6 of 2244 patients on beta-blockers had malaria (P value < 0.001)

Conclusions Usage of beta-blockers is associated with a significant decrease in the incidence of malaria.

AIMS AND OBJECTIVES

AIM:

The aim of the study was to determine if usage of beta-blockers was associated with a statistically significant decrease in the incidence of malaria.

OBJECTIVES:

The objectives of the study were

1. to find the incidence of malaria in patients attending the follow up clinics of Hypertension and Cardiology departments of the Government Royapettah Hospital and to calculate, from the above data, the incidence of malaria in patients already on beta-blockers and in those not on beta-blockers,
2. to find the difference in incidence rate among the two groups and
3. to determine its statistical significance.

REVIEW OF LITERATURE

History of the disease:

Malaria occupies a unique place in the annals of history. Over millennia, its victims have included Neolithic dwellers, early Chinese and Greeks, princes and paupers. In the 20th century alone, malaria claimed between 150 million and 300 million lives, accounting for two to five percent of all deaths. Although its chief sufferers today are the poor of sub-Saharan Africa, Asia, the Amazon basin, and other tropical regions, 40 percent of the world's population still lives in areas where malaria is transmitted.

Ancient writings and artefacts testify to malaria's long reign.

Malaria antigen was recently detected in Egyptian remains dating from 3200 to 1304 BCE.

Indian writings of the Vedic period (1500 to 800 BCE) called malaria the "king of diseases". In the Susrutha Samhitha, a Sanskrit medical treatise, the symptoms of malarial fever were described and attributed to the bites of certain insects.

Malaria became widely recognised in Greece by the fourth and fifth century BCE and it was responsible for the decline of many of the city-state populations.

Hippocrates noted the principle symptoms. He classified the fever types as quotidian (daily), tertian (alternate days) and quartan (fever three days apart). He also noticed that those who drank the stagnant marsh water had large stiff spleens, a characteristic of the disease, and fatal dropsy was common among them. By the age of Pericles, there were extensive references to malaria in the literature and depopulation of the rural areas was recorded.

The Greek poet Homer mentions malaria in The Iliad. He linked the appearance of Sirius, the Dog Star (in late summer and autumn) with

malarial fever and misery. Aristophanes mentions the disease in *The Wasps*. Philosophers like Plato (428-347 BCE), Sophocles (496-406 BCE) and Aristotle (384-322 BCE) too have mentioned it.

Spread of the disease:

Spread to Europe:

Malaria's probable arrival in Rome in the first century CE was a turning point in European history.

From the African rain forest, the disease most likely travelled down the Nile to the Mediterranean, then spread east to the Fertile Crescent, and north to Greece. Greek traders and colonists brought it to Italy. From there, Roman soldiers and merchants would ultimately carry it as far north as England and Denmark.

Spread across Europe:

For the next 2000 years, wherever Europe harboured crowded settlements and standing water, malaria flourished, rendering people seasonally ill, and chronically weak and apathetic.

Many historians speculate that falciparum malaria (the deadliest form of malaria species in humans) contributed to the fall of Rome. The malaria epidemic of 79 CE devastated the fertile, marshy croplands surrounding the city, causing local farmers to abandon their fields and villages. As late

as the 19th century, travellers to these same areas remarked on the feebleness of the population, their squalid life and miserable agriculture. The Roman Campagna would remain sparsely settled until finally cleared of malaria in the late 1930s.

Spread to Asia:

In India and China, population growth drove people into semitropical southern zones that favoured malaria.

India's oldest settled region was the relatively dry Indus valley to the north. Migrants to the hot wet Ganges valley to the south were disproportionately plagued by malaria and other mosquito and water borne diseases.

Millions of peasants who left the Yellow River for hot and humid rice paddies bordering the Yangtze encountered similar hazards. Due to the unequal burden of disease, for centuries, the development of China's south lagged behind its north.

Spread to the New World:

Although some scientists speculate that vivax malaria may have accompanied the earliest New World immigrants who arrived via the Bering Strait, there are no records of malaria in the Americas before

European explorers, conquistadores and colonists carried *Plasmodium malariae* and *P. vivax* as microscopic cargo.

Falciparum malaria was subsequently imported to the New World by African slaves initially protected by age old genetic defences (sickle cell anemia, and G6PD deficiency) plus partial immunity gained through lifelong exposure. Their descendants, as well as Native Americans and settlers of European ancestry, were more vulnerable, however. Deforestation and "wet" agriculture such as rice farming facilitated breeding of *Anopheles* mosquitoes.

By 1750, both *vivax* and *falciparum malaria* were common from the tropics of Latin America to the Mississippi valley to New England.

Malaria, both epidemic and endemic, continued to plague the United States until the early 20th century. It struck presidents from Washington to Lincoln, and did not spare the common man. It was brought under control once effective sanitary measures were implemented and the vector mosquitoes were controlled. But the disease persists to plague the world.

Discovery of the parasite:

Charles Louis Alphonse Laveran, a French army surgeon stationed in Constantine, Algeria, was the first to notice parasites in the blood of a

patient suffering from malaria. This occurred on the 6th of November 1880. For his discovery, Laveran was awarded the Nobel Prize in 1907.

Discovery of the antimalarial drugs:

In China, during the second century BCE, the Qinghao plant (*Artemisia annua*) was described in the medical treatise 52 Remedies, found in the Mawangdui Tomb. In 340 CE the anti-fever properties of Qinghao were first described by Ge Hong of the East Yin Dynasty.

The active ingredient of Qinghao was isolated by Chinese scientists in 1971. Known as artemisinin, it is today a very potent and effective antimalarial drug, especially in combination with other medicines.

The problem at present:

World perspective:

Of the total population of the world, 2.4 billion are at risk. The incidence of the disease ranges between 300 and 500 million per year with 90% in sub-Saharan Africa.

The yearly loss of life is estimated to be between 1.1 and 2.7 million people, of which 1 million are children below five years of age, contributing to 25% of child mortality in Africa.(1)

The scenario in the South East Asian Region:

The predominant causal organism in the south east Asian regions is *P. vivax* followed by *P. falciparum*. 1.3 billion people or 85% of the population of the region are at risk; 20 to 23 million are infected; 30% live in areas with moderate to high risk - mainly in India, Myanmar, and Thailand.(2)

Intracellular Parasite Invasion Strategies:

Intracellular parasites use various strategies to invade cells and to subvert cellular signalling pathways and, thus, gain a foothold against host defences. Efficient cell entry, ability to exploit intracellular niches, and persistence make these parasites treacherous pathogens.

Most intracellular parasites gain entry via host-mediated processes, but apicomplexans use a system of adhesion-based motility called "gliding" to actively penetrate host cells. Actin polymerization-dependent motility facilitates parasite migration across cellular barriers, enables dissemination within tissues, and powers invasion of host cells. Efficient invasion has brought widespread success to this group, termed Apicomplexans, which includes *Toxoplasma*, *Plasmodium*, and *Cryptosporidium*.(3)

Overview: Invasion involves a clear cascade of independent events.

- Initial long range contact is made by means of relatively non specific mechanisms, including electrostatic interactions.
- Thereafter, a tight binding follows. Major ligands in this interaction are: for *P. falciparum*, erythrocyte Binding Antigen 175(EBP 175) and Glycophorin A amongst others; and for *P. vivax*, EBA 140 and Duffy antigen.
- At this point, the tight junction between the parasite and the host cell form a protein rich domain in the host membrane in the form of a belt around the tip of the merozoite.
- This tight junction is then driven by the merozoite actin-myosin matrix against the cytoskeleton of the parasite towards the posterior of the cell, thus pushing the merozoite into the RBC. (4)

Components: The apicomplexans have developed sophisticated multiprotein machinery for entering multiple cell types in the human host and the insect vector. For malarial parasites, the major motor components of this machinery appear to be the same for entering, and leaving, insect cells as well as human host hepatocytes and erythrocytes.

During invasion by malarial parasites, adhesive transmembrane proteins bind to the host cell and are linked to the invasive motor via an

interaction between the cytoplasmic tail of the transmembrane proteins and aldolase, which in its turn interacts with actin. (5)

Invasive motor: The parasite invasive motor is composed of actin and an Apicomplexan-specific myosin molecule, MyoA. This parasite-encoded actin-myosin A-MTIP (MyoA-tail-interacting protein) motor is present in all Apicomplexans. Studies of MyoA in *Toxoplasma* have demonstrated its essential role in parasite invasion and gliding motility. (5)

MTIP Vs Calmodulin family: A protein assembly, of which the MyoA-tail-interacting protein (MTIP) is a key member, tethers the motor to the inner membrane complex (IMC). MTIP shows distant sequence homology to the myosin light chains and calmodulin family even though MTIP misses the canonical calcium-binding motif present in many members of this protein family.

The binding of MTIP from *Toxoplasma gondii* and from *Plasmodium* species to Apicomplexan myosin is uniquely mediated via the tail of MyoA rather than via the neck region as is the case with muscle myosin interacting with the myosin light chain. A combination of hydrophilic and hydrophobic interactions is responsible for forming the complex between the tail and the tail-binding protein. (5)

Mechanism of the Invasion:

- MTIP binds the tail of MyoA, which localizes MyoA to the IMC. Additionally, MTIP is tethered to the IMC via an interaction with the GAP45-GAP50 complex, with GAP50 being an integral membrane protein of the IMC.
- The head domain of MyoA interacts with the short actin filaments that are indirectly linked via an aldolase tetramer to the cytoplasmic domain of a transmembrane protein, which binds the cell being invaded via its exocellular adhesive domains.
- Because the position of MyoA is fixed on the IMC, the action of the myosin head domain results in the actin-aldolase-transmembrane protein complex being displaced toward the posterior end of the parasite, resulting in forward movement of the parasite. (5)

Thus, it has been found that G proteins in the RBCs are used by the parasite during entry into the cell. Two major Gs associated receptors, the beta-adrenergic and the adenosine receptors are known to be present in RBCs. Researchers have been able to show that stimulating these receptors with agonists increased the infection of the RBCs while beta-

blockers which are antagonists, prevented the parasite from entering the RBCs.(6) .

G proteins are distinct heterotrimeric GTP binding regulatory proteins and function as signal transducers that convey information from the receptor to one or more effector proteins.(7)

G protein coupled receptors (GPCRs) are a large superfamily of receptors that include those for a number of biogenic amines, eicosanoid and other lipid signalling molecules, peptide hormones, opioids, amino acids, peptides and protein ligands. G protein regulated effectors include enzymes such as adenylyl cyclase, phosphorylase C, phosphodiesterase and plasma membrane ion channel such as for Ca and K. (7)

All the adrenergic receptors are GPCRs that link to heterotrimeric G protein. Each major type shows preference for a particular class of G protein, i.e., alpha1 to Gq, alpha2 to Gi and beta to Gs. These systems involve three proteins - the GPCRs, the coupling G protein and the effector enzyme or ion channel. All three beta receptor subtypes (1, 2, 3) couple to Gs and activate adenylate cyclase. (8)

Autonomic Nervous System:

The motor (efferent) portion of the nervous system can be divided into two major subdivisions: autonomic and somatic. The autonomic nervous system is largely independent in that its activities are not under direct conscious control. It is concerned primarily with visceral functions - cardiac output, blood flow to various organs, digestion, etc. - that are necessary for life. It has two divisions - sympathetic and parasympathetic. The end neurotransmitters usually involved in sympathetic pathway are the catecholamines.(9)

Identification of the Adrenoceptors:

The effort to understand the molecular mechanisms by which catecholamines act has a long and rich history. A great conceptual debt is owed to the work done by John Langly and Paul Ehrlich 100 years ago in developing the hypothesis that drugs have their effects by interacting with specific 'receptive' substances. (10)

Raymond Ahlquist in 1948 rationalized a large body of observations by his conjecture that catecholamines acted via two principal receptors. He termed these receptors alpha and beta.(10)

Soon after the demonstration of separate alpha and beta receptors, it was found that there were at least two subtypes of beta receptors, designated beta1 and beta2. They are operationally defined by their affinities for epinephrine and norepinephrine. Beta1 receptors have approximately equal affinity for epinephrine and norepinephrine, whereas beta2 receptors have higher affinity for epinephrine than norepinephrine.

(10)

Molecular mechanism of sympathomimetic action:

The effects of catecholamines are mediated by cell surface receptors- alpha, beta. These receptors are coupled by G proteins to various effector proteins whose activities are regulated by those receptors.

Each G protein is a heterotrimer consisting of alpha, beta and gamma subunits. G proteins of particular importance for adrenoceptor function include Gs, the stimulatory G protein of adenylyl cyclase; Gi, the inhibitory G protein of adenylyl cyclase; and Gq, the protein coupling alpha receptors to phospholipase C.

The activation of G protein coupled receptors by catecholamines promotes the dissociation of GDP from the alpha subunit of the appropriate G protein. GTP then binds to this G protein and the alpha subunit dissociates from the beta-gamma unit. The activated GTP bound

alpha subunit then regulates the activity of its effector. Effectors of adrenoceptor activated alpha subunit include adenylyl cyclase, cGMP phosphodiesterase, phospholipase Catecholamines, and ion channel. (11)

Adrenoceptor Antagonistic drugs:

Beta adrenoceptor antagonist drugs have been found useful in a very wide variety of clinical conditions and are firmly established in the treatment of hypertension, ischemic heart disease, arrhythmia, endocrinological and neurologic disorders. The clinical use of these drugs include both of the selective and non selective kind, depending on the condition for which they are prescribed.

Atenolol:

This is a beta1 selective antagonist that is devoid of intrinsic sympathomimetic and membrane stabilizing activity.

It is incompletely absorbed (about 50%), but since the first pass metabolism at the liver is low, most of the absorbed dose reaches the systemic circulation. The elimination half-life from the plasma is between 5-6 hours. There is relatively little interindividual variation in plasma concentration.

The usual antihypertensive dose is 50 mg / day given once daily. It may be increased to 100 mg/day, if response is inadequate. (12)

Metoprolol:

This is a beta₁ selective receptor antagonist that is devoid of intrinsic sympathomimetic activity and membrane stabilizing activity.

It is almost completely absorbed after oral administration but bioavailability is low because of first pass metabolism. Plasma concentration vary widely. The half life of metoprolol in the blood plasma is 3 - 4 hours.

The usual initial dose for hypertension is 100 mg/day taken once or twice daily. It is generally given in two divided doses for angina. (13)

Propranolol:

This is the prototypical beta blocker.

It interacts with beta₁ and beta₂ receptors with equal affinity, lacks intrinsic sympathomimetic activity.

Propranolol is almost completely absorbed after oral administration. However, most of the drug is metabolised by the liver and usually only 25% reaches the circulation. There is a great interindividual variation in the presystemic clearance of propranolol by the liver. Its half life in plasma is 4 hours.

In treatment of hypertension and angina, the initial oral dose is generally 40 - 80 mg/day and may be increased to a maximum of 320 mg/day. (14)

MATERIALS AND METHODS

Design:

This was a prospective study.

Period:

This study was conducted during the period between May 2004 and August 2006.

Participants:

The participants were the patients who were attending the follow up clinics of Hypertension and Cardiology. These clinics are held on a fortnightly basis.

Questionnaire:

The form used to interview the patients is appended with this record. The information obtained included the following:

1. name of the patient
2. age
3. sex
4. registration number
5. whether on beta blocker or not - if on beta-blocker then, the drug
and the dose;
6. fever anytime within the past fourteen days, i.e., from the time
when the patient was last interviewed, and if positive, then
presence or absence of periodicity, hot phase, cold phase,
wet phase, spleen, pallor, smear proven diagnosis of malaria,
treatment with antimalarial medicines and response thereof,
if any;
7. evidence of other causes of fever like focal sepsis,
dermatological diseases, history of recent surgery or invasive
procedure, Cardiac valvular pathology,
immunocompromised state (chronic liver disease, chronic
kidney disease, AIDS, on long term steroids, history of
splenectomy).

Diagnosis of Malaria:

The patient was diagnosed to have suffered from malaria if either of the two following conditions were met.

1. peripheral smear revealing malarial parasite
2. typical history of periodical high grade fever, with hot, cold and wet phases, with an enlarged spleen, and response to antimalarial medicines; with absence of focal sepsis, dermatological diseases, history of recent surgery or invasive procedure, Cardiac valvular pathology, immunocompromised state (chronic liver disease, chronic kidney disease, AIDS, on long term steroids, history of splenectomy), or any other obvious cause of fever.

Analysis of the Data:

The information so gathered from the questionnaire was summarised and the patients were grouped into four categories

1. those not on beta-blockers, without malaria
2. those not on beta-blockers, with malaria
3. those on beta-blockers, without malaria and
4. those on beta-blockers, with malaria.

The significance of the difference in incidence was assessed using the chi-square test as detailed further in the chapter on statistical analysis.

6. RESULTS

4400 patients were interviewed during the course of the study. The detailed list is appended with this record.

The distribution of the patients according to sex - whether male or female was as follows

Table 6.1. Distribution according to sex

S. No.	Sex	Number
1.	Male	2436
2.	Female	1964

The distribution of the patients by way of the age was as follows. The data is presented with a period interval of ten years for easier understanding.

Table 6. 2. Distribution according to age

S. No.	Age	Number
1.	<20 Years	0
2.	21 - 30 Years	6
3.	31 - 40 Years	336
4.	41 - 50 Years	1064
5.	51 - 60 Years	1520
6.	61 - 70 Years	1074
7.	71 - 80 Years	398
8.	81 - 90 Years	2
9.	>90 Years	0

The distribution of the patients based upon whether they were on beta-blockers or not is as follows

Table 6.3. Distribution by beta-blocker therapy

S. No.	Patients	Number
1.	On beta-blocker	2244
2.	Not on beta-blocker	2156

The number of patients taking various compounds of beta-blockers is given below

Table 6.4. Distribution by beta-blocker type

S. No.	Beta-blocker	Number
1.	Atenolol	2166
2.	Propranolol	70
3.	Metoprolol	8

Further, the distribution of the patients who were on beta blockers and those who were not, according to the sex was as follows.

Of the 2436 male participants, the number who were on beta-blockers and those who were not is shown in the following table.

Table 6.5. Distribution of male according to beta-blocker usage.

S. No.	Male patients	Number
1.	Not on beta-blockers	970
2.	On beta-blockers	1466

Similarly, the 1964 female patients were also put in two categories as given below.

Table 6.6. Distribution of female patients according to beta-blocker usage

S. No.	Female patients	Number
1.	Not on beta-blockers	1186
2.	On beta-blockers	778

The distribution of the patients with regard to presence or absence of fever is given below.

Table 6.7. Distribution by fever

S. No.	Patients	Number
1.	With fever	291
2.	Without fever	2109

The number of patients suffering from various causes of fever is as follows.

Table 6.8. Distribution by fever type

S. No.	Fever	Number
1.	Viral fever with arthralgia	98
2.	URI	101
3.	UTI	30
4.	Malaria	48
5.	Others	20

7. STATISTICAL ANALYSIS

First objective: This was to find the incidence of malaria among patients on beta-blockers and those not on beta-blockers.

It was achieved by tabulating the results as given below

Table 7.1. Distribution of patients according to incidence of malaria and by intake of beta-blocker.

Patients	Without Malaria	With Malaria	Total
Not on Beta-blocker	2114	42	2156
On beta-blocker	2238	6	2244
Total	4352	48	4400

Second objective: This was to find the difference in the rate of incidence of malaria among patients on beta-blocker when compared to that among the patients not on beta-blocker.

Table 7.2. Incidence rate among the two groups

Patients	Without Malaria	With Malaria	Total	Incidence rate
Not on beta-blocker	2114	42	2156	1.95 %
On beta-blocker	2238	6	2244	0.27 %
Total	4352	48	4400	1.10 %

Since there was a difference in the incidence rate, we proceeded on to the next objective.

Third objective: This was to calculate the significance of the difference in the incidence rate. This was done by using the chi-square (χ^2) test.

Chi-square (χ^2) Test:

This was done by forming a Null Hypothesis and verifying whether it was true or false.

Null Hypothesis:

This stated that the difference in the incidence rate was not significant.

Verification:

The purpose was to either prove or disprove the Null Hypothesis. This consisted of 7 steps.

Step 1. The incidence rate when both group are considered together was calculated - i.e., the proportion of the patients with malaria to the total number of patients.

$$\begin{aligned}\text{Incidence rate} &= \frac{\text{Total no. of patients with malaria}}{\text{Total number of patients}} = \frac{0048}{4352} \\ &= 1.10 \%\end{aligned}$$

Step 2. The number of patients in each group who would be expected to have malaria given this incidence rate was then calculated. The values are calculated from this incidence rate and the values from the table 7.2. The values so calculated have been represented in a tabular column as in the following table.

Table 7.3. Expected values in each category

Patients	Without Malaria	With Malaria	Total
Not on beta-blocker	2132.3	23.7	2156
On beta-blocker	2219.3	24.7	2244
Total	4351.6	48.4	4400

Step 3. The difference between the observed value and the expected value in each category was calculated. These values are tabulated below.

Table 7.4. Difference in each category.

Patients	Without Malaria	With Malaria
Not on Beta-blocker	- 18.3	+18.3
On Beta-blocker	+ 18.7	- 18.7

Step 4. The value of χ^2 was calculated from the above data using the formula $\chi^2 = \Sigma (\text{observed value} - \text{expected value})^2 / \text{expected value}$

The value of χ^2 was found to be 28.6

Step 5. The degree of freedom for the above table was calculated. It was found to be 1.

Step 6. Next, the probability for a χ^2 value of 28.6 and one degree of freedom was noted using the probability table. It was found to be < 0.001 (for a χ^2 value > 10.83 , p value is < 0.001)

Step 7. For the observed value to be within the limits of normal variation from the expected value, the p value should be > 0.05 . Here, the p value is < 0.001 . Thus, the observed value lies well beyond the confidence limits.

Therefore, the Null Hypothesis was proved false, i.e., the difference in the incidence rate is statistically significant, with a p value of < 0.001 .

Thus, the third objective was also achieved.

8. DISCUSSION

Relevance of the Study:

Malaria is a major health problem that the world is facing. The morbidity and the mortality associated with it causes loss of man power and compromises the quality of life.

In spite of newer compounds being formulated against the parasite, they are generally only as effective as the original antimalarials like quinine. In many instances, by the time the patient seeks medical attention, the disease has already affected vital organs like the brain and liver, and the resuscitative measures are in vain. More commonly, the patient's daily

routine is affected and valuable man power is lost. Thus it is imperative that ways be found to prevent the illness rather than just concentrating our efforts in curing it.

Vaccines have been the mainstay in prevention of most diseases. But in the case of malaria, development of an effective vaccine has not been possible as yet.

Chemoprophylaxis is another way of preventing disease. In the recent past, research has been done on the invasion strategies of the parasite, where mechanisms adopted by the parasite to enter the host cells have been elucidated. Further research has also revealed that beta adrenergic receptor related G proteins are utilised by the parasite and that blocking of these receptors prevented the entry of the parasite.

Beta-blockers are reasonably economical and safe with relatively few contraindications. If found effective, usage of these drugs could be encouraged and protocols formulated for use in target populations, in

endemic areas, during high transmission seasons, by travellers to endemic areas and if indicated and feasible, for the general population.

As of the time when this study was begun, there had been as yet no published data as to the preventive effect of beta-blockers on malaria in the clinical scenario. During the last months of the study period, a retrospective study done at Manipal Academy of Higher Education, Karnataka was published in the British Medical Journal. The results of that study and that of ours is further discussed later on in this chapter.

If the results of this study were found to be significant then further research and resource could be directed in this direction.

Study Design:

This was a prospective study.

Since malaria is an acute febrile illness, usually lasting a short duration only, the incidence of malaria and usage of beta-blockers were noted during the high transmission period and then analysed.

This was of the observational type and not experimental because no drug was added to or removed from the medicines already being consumed by the patient.

Participants:

They were the patients attending the follow up clinics of hypertension and cardiology.

This group was chosen because many of them would be on long term beta-blocker therapy, and it would be possible to follow them up and re-evaluate regularly. In addition, the participants would be comparable for age, sex, gender, socio economic strata, area of residence, co-morbid illnesses and other drugs intake.

This way, confounding factors could be decreased and skewing of data minimised.

Questionnaire:

The first four questions pertained to the patient's general information like the name, sex, age and registration number.

The fifth question was regarding the drug therapy - whether the patient was on beta-blockers or not. This was one of the two essential variant (the other being whether the patient suffered from malaria) required of the patient for this study to be done. In addition, if the patient was on beta-blockers, then the specific compound used and the dosage consumed was recorded. This information may be useful in further assessing the minimum amount of drug necessary to prevent the parasite invasion and also to know whether there were any differences between the protective effects of compounds used.

The sixth question dealt with the other essential variant - whether the patient was suffering from malaria or had had the disease since the last time he had been assessed by the interviewer. Discussion regarding the diagnosis of malaria follows.

Diagnosis of Malaria:

This required either of the two following conditions to be met.

Condition 1. Peripheral smear examination showing malarial parasite. This would be a confirmed, slide proven diagnosis. This is the classical method and recommended by the reference texts.

Condition 2. This had two components as given below.

- A history typical of malarial fever, including high grade fever, periodicity, hot phase, cold phase, wet phase, with an enlarged spleen and pallor, and response to antimalarial medicines.
- For this condition to be fulfilled there had to be no evidence of any other cause of fever - such as focal sepsis; dermatological diseases; history of recent surgery or invasive procedure; cardiac valvular pathology; immuno-compromised states such as chronic liver disease, chronic kidney disease, AIDS, glucocorticoid intake.

The second condition was included for making a diagnosis of malaria because, in many instances, the patient, on developing fever, would have consulted the local medical practitioner and obtained treatment, thus would have a non informative peripheral smear picture at the time of follow up with us. In such patients, we followed the malarial score suggested by various studies conducted under the behest of the WHO.

The specificity of such scoring for the diagnosis of malaria when all the above features are present is high as evidenced by studies quoted and discussed below.

Chandramohan et al conducted a study regarding the validity of a clinical algorithm for the diagnosis of malaria. The various parameters included were chills, feeling cold, vomiting, absence of cough, absence of runny nose, absence of diarrhoea, patient feels hot to touch, palpable spleen, palpable liver, temperature > 37 degrees centigrade. Each condition, if true was assigned a value of one. The sum of all the values for the patient was taken as the malaria score. A score of seven had a sensitivity of 11% and a specificity of 94.9% (15)

There have been other studies conducted along similar lines.

Genton et al conducted a similar study in which the factors taken into consideration were fever, palpable spleen, no cough, no vomiting. The specificity for the diagnosis of malaria in adults with these features was found to be 99.8 % (16)

Redd et al found that the presence of fever of more than 38⁰ C with a palpable spleen or pallor of the nail bed had a specificity of 99.8% for the diagnosis of malaria.(17)

Rougemont et al, in their study concluded that fever of more than 39⁰ C lasting less than three days, with no other obvious cause had a specificity of 98.6 % for the diagnosis of malaria.(18)

Distribution by Age:

This distribution is seen to follow the normal bell shaped curve. The maximum number of patients were in their sixth decade of life. There is also an almost symmetrical distribution of patients aged higher and lower.

The morbidity and mortality associated with malaria is higher in children and young adults when compared with the middle aged and elderly adults. The study participants belonged to the latter group. This was an inevitable consequence because of the nature of the disease for which they were getting long term treatment. Both hypertension and cardiac

disease are usually ailments of advancing age. Nevertheless, both the groups of patients being considered - that on beta-blockers and that not on beta-blockers were comparable for the distribution by age.

Distribution by Sex:

It is seen that the number of male patients was higher than that of the females. This again could be because of the nature of the primary ailment for which they were on treatment. Even so, the numbers of patients on beta-blockers and not on beta-blockers within each sex category were comparable.

Distribution by Beta-blocker Type:

The compounds used by the patients were atenolol, metoprolol and propranolol.

The compound maximally prescribed is seen to be Atenolol when compared with the other compounds. This is probably because Atenolol is subtype specific and quite readily available at the government hospitals.

Propranolol, on the other hand, though the prototypical beta-blocker, is used only sparingly, probably because of its non-selective nature. It was seen to be used for certain uncommon diseases like symptomatic mitral valve prolapse.

Metoprolol is the least used of all the beta-blockers, though subtype specific, because of its non-availability in the government hospitals.

The dosage of the medications were usually once a day, and occasionally twice a day.

Distribution by Fever Type:

The majority of patients had fever because of infections. As expected of any out patient department, the respiratory tract infection and viral infections predominated.

The commonest cause of fever is seen to be upper respiratory tract infection. This could be due to the fact that the study periods were during the high transmission season of the monsoon time when the incidence of such infections like sinusitis, rhinitis, pharyngitis usually increases.

The next most common cause of fever in our study is the short lasting, self limiting, high grade fever associated with sever joint pain, muscle pain, and occasionally joint swelling with normal routine hematological,

serological, biochemical parameters. This could be caused by a virus related to the chikungunya virus and was termed viral fever with arthralgia.

Malaria is found to be the third commonest cause of fever. This high incidence could be explained because of the period of study being in the high transmission season.

The other cause is urinary tract infection. This category included infection of the urethra, the bladder, the ureter and the kidneys. The commonest infection was of the urethra. This infection is seen to have affected the females more, as should be expected because of the difference in anatomy.

Other causes of fever include focal sepsis such as skin infections, otitis, lower respiratory tract infections, gastro enteritis.

About the Analysis:

Objectives 1, 2, 3: The incidence of malaria among patients not on beta-blockers is found to be six times that among patients on beta-blockers in spite of the number of patients being lesser in the former group. The chi square test was used to analyze this difference and find the significance.

About the p value:

In our test, the p value is found to be < 0.001 . A p value of < 0.05 is significant and denotes deviation of more than 2 standard deviations from the mean. Thus the p value obtained in our study clearly indicates that the incidence of malaria in the group of patients on beta-blockers is significantly lesser than that in the group of patients on beta-blockers.

Further discussion of the results of the analysis:

Beta-blocker usage is associated with a statistically significant decrease in the incidence of malaria.

This result is along the expected lines. In vitro research proved that parasitic invasion of cells was inhibited by beta-blocker usage. The results of this study reveal the clinical aspect of the same effect.

Unfortunately, despite extensive searching, we could come upon only one other study conducted with a similar aim. This was conducted at the Manipal Academy of Higher Education, Karnataka. It was a retrospective study where in the hospital records were analysed and the association between beta-blocker usage and the incidence of malaria was evaluated.

The results of that study also prove that beta-blocker usage is associated with a decreased incidence of the disease.

The method followed in our study is different entirely, ours being a prospective study, measuring the incidence of malaria in a group of patients already on long term beta-blocker therapy.

Nevertheless, both the studies have proved the statistical significance of the decrease in incidence.

Deficiencies of this Study:

Malaria is disease with its most florid manifestations and effects on the pediatric population. But for obvious reasons as stated above, our study could not include this age group. The results would have been more relevant had the pediatric population too been included.

The diagnosis of this disease is confirmed only by the presence of the malarial parasite on examination of the blood smear - either of the peripheral blood or, if needed, the bone marrow. But in our study, we have also included patients who have all the features as given in the malarial score. Even though the specificity of the scoring is high if all the

variables are present, the chance of a false positive diagnosis cannot be conclusively excluded.

What next?

It would be prudent to conduct large, multi-centered studies of similar nature to verify the results of this study and then direct efforts in doing experimental research with well designed clinical trials focusing on the preparations effective in this respect and the least dosage required.

CONCLUSION

Among the patients attending the follow up clinics of hypertension and cardiology during the high transmission season, there is a statistically significant decrease in the incidence of malaria among those on beta-blocker therapy when compared with those not on beta-blocker therapy.

In other words, beta blocker usage is associated with a statistically significant decrease in the incidence of malaria.

SUMMARY

With recent research elucidating the invasion strategies of intracellular parasite and in-vitro studies proving that beta-blockers inhibit the invasion, it is essential that effort is directed towards evaluating the effect of these compounds on the incidence of malaria in the clinical scenario.

Since the aim of the study was to calculate the incidence rate, it was decided to do a prospective observational data collection.

The participants were patients who attended the follow up clinics of hypertension and cardiology, thus minimising skewing of data and decreasing confounding factors.

The maximum number of patients belonged to the sixth decade of life and the distribution followed the normal bell shaped pattern.

The incidence of malaria was found to be significantly decreased in patients who were on beta-blockers when compared with those not on beta-blockers, thus the clinical relevance of the results of the earlier in-vitro studies is highlighted.

The results of this study would have been more compelling had the population of the paediatric age group also been included, and if we could have had smear examination proven malaria in all the cases of suspected disease.

The case for the beneficial role of beta-blockers in decreasing the incidence of malaria has only been made stronger by this study. Nevertheless, it is desirable that further suitably designed research is done in this direction in order to fully exploit the potential of the promise held by the beta-blockers in this regard.

APPENDIX - I : Questionnaire

1. Name

2. Age

3. Sex

4. Op. No.

5. Whether on beta-blockers: Yes / No

if yes, then, a. the compound taken:

b. the dosage

6. History of fever: Yes / No

if yes, then a. periodicity y/n

b. hot phase y/n

c. cold phase y/n

d. wet phase y/n

e. spleen y/n

f. pallor y/n

g. smear positive for malaria y/n

h. treatment with anti malarials y/n

and response.

7. Evidence of other causes of fever Yes / No

focal sepsis, dermatological diseases, history of recent surgery or
invasive procedure, Cardiac valvular pathology,
immunocompromised state (chronic liver disease, chronic kidney
disease, AIDS, on long term steroids, history of splenectomy).
